

The head and heart connection

Et prosjekt om hjertepasienters psykisk helse

—●— Women
—■— Men
— 95% Confidence Interval

/ PHYSICAL DISEASE AND RISK FACTORS

23%

Illness accounted for 23% of variation. It lowers SRH whenever in life it occurs. 2 or more comorbid diseases increases this effect.

/ MENTAL HEALTH SYMPTOMS

28%

Mental health accounted for 28% of the variation and is the most important factor for Significant symptoms lowers the SRH levels more than physical disease.

/ GENDER AND AGE

21%

It is actually age that is the most important as gender accounts for only 0.4%. The most interesting gender difference is that men report higher SRH at 25, but women remain at good health longer.

/ HEALTH RELATED BEHAVIOR

17%

Nothing can stop the age dependent SRH decline; however, even moderate exercise levels prolongs the period subjects are at good health by 10 years or more. Intensive training after 63 years of age was not beneficial

/ BODY WEIGHT

5%

BMI is not the most important factor as such explaining 5% of the variation. Obesity is not beneficial. However, the most significant finding is what happens to very lean persons as they get older.

/ SOCIO-ECONOMIC CONTEXT

16%

Accounting for 16%, higher education levels is beneficial. Living with others is generally also beneficial.

The characteristics of SRH has changed as the «objective» public health situation has improved

Symptoms of anxiety and depression associated with disease increases in the periode from T4 to T6

Modellering av tid

- Hvis vi nå skulle plote inn utviklingen for hver enkelt person ville vi fått ulike linjer alla dette
- Det vi ønsker å gjøre er å integrere de longitudinelle trendene i disse forløpene inn i vår modell

Methods to utilize repeated measures

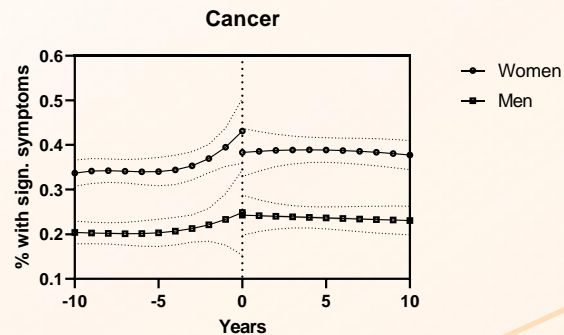

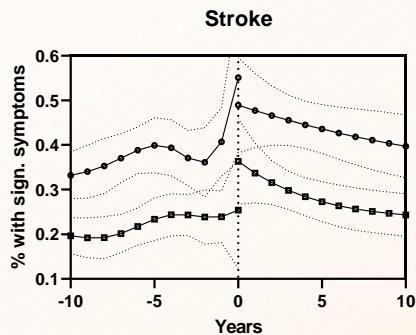

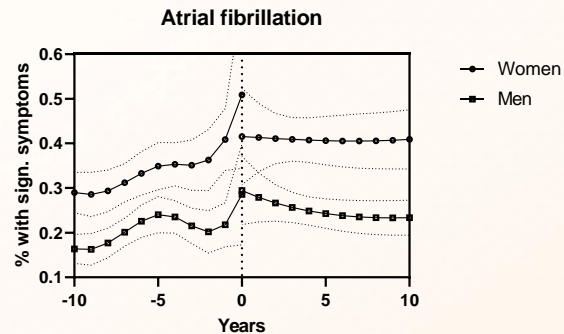

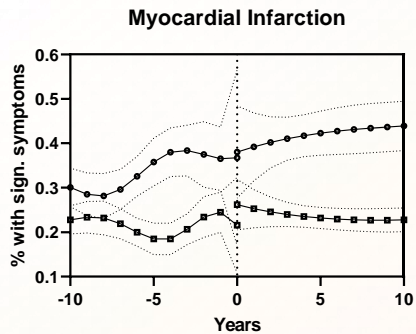

Tracking the population

- Repeated x-sections
- X-sectional time series

Tracking individuals with multilevel modeling

- Fixed effects: Within subject effects
- Mixed model: within- and between-subjects effects
- Inverse probability weights to control for prior exposure and attrition

Utvikling over tid: Tiden før og etter første diagnose

Tracking individuals with multilevel modeling

Hvilke faktorer bør følges opp?

Kvinner er mer utsatt

Yngre er mer utsatt

Komorbide sykdommer gir en risiko (OR 1.22-1.39)

Hypertensjon og Diabetes MT2 gir økt risk

Helserelatert atferd beskytter

- ▶ The accelerated longitudinal design with 21 years of follow-up time allows us to link mental health trajectories to the onset of cardiovascular disease (CVD).
- ▶ A large cohort allows us to relate health, lifestyle and social factors to mental health outcomes.
- ▶ A population study design with a high participation rate and a validated endpoint register allows us to relate our findings to a general population.
- ▶ Self-reported mental health could induce measurement errors because specific cardiovascular outcomes are not easily differentiated from symptoms of mental disease.
- ▶ The (inverse) causality of CVD and mental health has never been demonstrated and calls for further studies that examine previous life factors and prediagnostic mental health trajectories.

BMJ Open Assessment of mental health trajectories before and after myocardial infarction, atrial fibrillation or stroke: analysis of a cohort study in Tromsø, Norway (Tromsø Study, 1994–2016)

Geir Fagerjord Loren ¹, Ida Marie Opdal ¹, Tom Wilsgaard ², Henrik Schirmer ^{3,4,5}, Maja-Lisa Locher,⁶ Ingrid Petrikke Olsen,^{7,8} Terje Staagen,^{1,4} Kamilla Rognum⁹

Abstract
Objectives: The increased survival rate of cardiovascular disease (CVD) implies a higher proportion of individuals who live with CVD. Using data from the Tromsø Study we aimed to investigate mental health symptom trajectories before and after myocardial infarction, atrial fibrillation or stroke in a general population and to explore factors that contribute to the associations.
Design: Cohort study.
Setting: Sample drawn from inhabitants of the municipality of Tromsø, Norway, who participated in the Tromsø Study (1994–2016).
Participants: A total of 18 173 participants (52.1% women) were included, and of these 2068 (32.0% women) were diagnosed with myocardial infarction, 1598 (41.5% women) with atrial fibrillation and 1262 (42.0% women) with stroke.
Primary outcome measures: Mental health symptoms were assessed using the Hopkins Symptom Checklist-10 and the Cox's Mental Health Index.
Results: The participants who were diagnosed with either myocardial infarction or stroke had a significant pronounced increase in mental health symptoms before myocardial infarction ($p=0.028$) and stroke ($p<0.028$) that intensified at the time of diagnosis. After the event, the study found a higher prevalence of mental health symptoms with a decline in symptom levels over time for myocardial infarction ($p<0.001$) and stroke ($p=0.004$), but not for atrial fibrillation before ($p=1.85$, after $p=0.410$). The risk of elevated mental health symptoms with myocardial infarction, atrial fibrillation and stroke was associated with sex ($p<0.001$), age ($p<0.001$), physical activity ($p<0.001$), diabetes ($p<0.05$) and other comorbidities ($p<0.001$).
Conclusions: The study indicates that mental health problems among individuals with myocardial infarction, atrial fibrillation and stroke may have started to develop several years before the cardiovascular event and suggests that successful CVD rehabilitation may need to consider previous life factors. Public research is recommended to examine whether health promotion measures in a general population also create mental health resilience after a CVD event.

Strengths and limitations of this study

- ▶ The accelerated longitudinal design with 21 years of follow-up time allows us to link mental health trajectories to the onset of cardiovascular disease (CVD).
- ▶ A large cohort allows us to relate health, lifestyle and social factors to mental health outcomes.
- ▶ A population study design with a high participation rate and a validated endpoint register allows us to relate our findings to a general population.
- ▶ Self-reported mental health could induce measurement errors because specific cardiovascular outcomes are not easily differentiated from symptoms of mental disease.
- ▶ The (inverse) causality of CVD and mental health has never been demonstrated and calls for further studies that examine previous life factors and prediagnostic mental health trajectories.

INTRODUCTION
Anxiety and depression are related to both onset and poorer outcomes of cardiovascular disease (CVD) worldwide. Epidemiological data suggest a 28.7% prevalence of depression among participants with myocardial infarction (MI),¹ which is far higher than in the general population (17.9%).² In addition, participants with atrial fibrillation (AF) have reported a high burden of depressive symptoms.³ Furthermore, one-third of stroke survivors develop depression,⁴ and one-quarter develop anxiety disorders.⁵ This study aims to enhance understanding of mental health among individuals with MI, AF and stroke, including an attempt to improve knowledge about mechanisms and factors associated with poor mental health in these participants. Epidemiological research suggests that depression in patients with coronary artery

How does Potential Traumatic Events affect CVD risk and mortality?

A mixed methods study of comorbid mental health problems among persons with myocardial infarction in the Tromsø study

Det er den samme populasjonen, men nå stratifisert utifra traumeeksponering

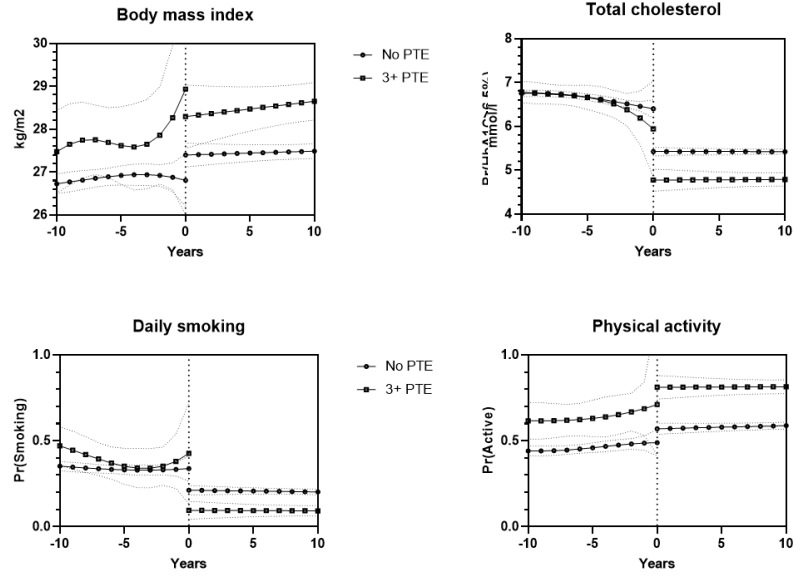

PTE innbærer økt risk for MI og all-cause death

MI hazard

Mortality hazard

MI hazard			Mortality hazard		
Lifetime PTE			Lifetime PTE		
Model 1			Model 1		
No PTE	1.000		No PTE	1.000	
1-2 PTE	1.186	(1.001 1.406)	1-2 PTE	1.127	(0.902 1.407)
≥3 PTE	1.516	(1.266 1.815)	≥3 PTE	1.611	(1.277 2.033)

Vi finner også at PTE modererer helsereelatert atferd

Vi ser at PTE er assosiert negativt til helsereelatert atferd og CVD risk faktorer FØR hjertehendelsen.

Etter hendelsen ser vi hvordan de får kontroll på kolesterol, blodtrykk, trener mer og slutter å røyke.

POST-TRAUMATIC STRESS SYNDROME AMONG HEART PATIENTS

A mixed methods study of comorbid mental health problems among persons with myocardial infarction in the Tromsø study

Bakgrunn

- Myocardial infarction (MI) kan oppleves som en livstruende situasjon og kan følgelig bli en potensielt traumatisk erfaring.
- Det er få studier omkring sykdomstraumer. Det er et forholdsvis nytt kriterium i DSM-5
- Andre studier viser et gjennomsnitt på 12% (range 0%-38%) prevalence av PTSD etter hjertestans.
- Angst og depresjon er sekundærsymptom for PTSD. Det kan altså være vanskelig å identifisere i klinisk praksis
- Vi ønsket derfor å undersøke **hvor mange av dem med angst og depresjonssymptomer i Tromsø 7 hadde PTSD?**

Our vision is that all heart patients regardless of diagnosis, receive proper treatment to mental health problems.

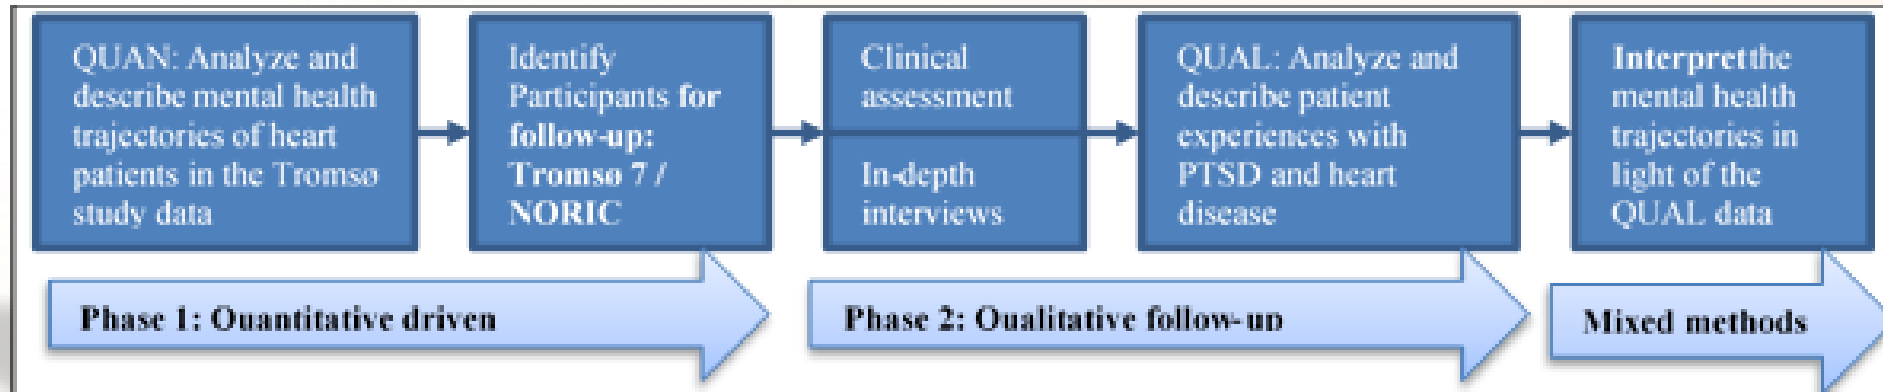

Figure 1. Flow chart showing the different phases of the study

We know that around a third of heart patients report clinically significant symptoms of anxiety/depression.

- We how many of them experience these problems due to PTSD.
- We invited individuals with a confirmed MI diagnosis to a clinical screening.
- The aim was to examine the prevalence of potential PTSD in MI patients.
- We also examined how PTSD symptoms were associated with PTE exposure.

21 % med minst moderate symptom og 12.9% med en sannsynlig PTSD

1. Vi fant **Ingen** sammenheng mellom sykdomstraume og PTSD.
2. Men det var en significant assosiasjon mellom **traumeeksponering og PTSD**
3. Clinicians should know that anxiety or depression symptoms after MI could be secondary symptoms of PTSD.
